Non-Thermal Plasma Techniques for Air Treatment

AOTs-5 Workshop on Advanced Oxidation Technologies: Fundamentals & Applications
May 24, 1999 - Albuquerque, NM

Louis A. Rosocha
Los Alamos National Laboratory

Abstract

To prevent toxic substances from entering and spreading through the environment and to meet increasingly stringent regulations, more effective methods of destroying chemical pollutants are being examined. Advanced oxidation processes, historically used for the treatment of recalcitrant water pollutants via hydroxyl radicals (OH), are now being applied to the treatment of gas-phase pollutants using non-thermal plasmas (NTPs). In NTPs, chemical decomposition can also be initiated by radicals other than OH, some of which may even be reductive rather than oxidative.

Non-thermal or non-equilibrium plasmas in gaseous media are characterized by combined energetic-electron (e.g., 1-10 eV) and low-temperature gas conditions. Free radicals, particularly oxygen-atom radicals, are effectively generated by NTPs and play a key role in the process of ozone generation (the historical source of OH for water treatment):

Other free radicals like the hydroxyl radical and nitrogen-atom radicals are also generated with NTPs in gases:

In the past several years, there has been increased interest in innovative pollution-control techniques. Researchers have explored the treatment of gas-phase pollutants with AOPs. Electric-discharge and electron-beam generated non-thermal plasmas are considered a promising technology for some applications, e.g., the removal of oxides of nitrogen and sulfur (NO_x and SO_x) and hydro/chloro-carbon volatile organic compounds (VOCs) from air-emissions streams:

In this talk, we will discuss non-thermal plasmas in the context of an AOP - namely a tool for free-radical-initiated decomposition reactions. The main points covered are the motivation for and applications of the process, background of atmospheric-pressure, non-thermal plasma processing for air-pollution control, figures-of-merit and cost examples, and representative application examples of the technology.

Program (SERDP)

Los Alamos —

Outline of talk

- Motivation for and applications of research
- Background of atmospheric-pressure, non-thermal plasma processing for environmental applications (air-pollution control)
 - ♦ Basics of radical formation & decomposition chemistry
 - ♦ Figures-of-merit & costs for decomposition of example pollutants
- Representative application examples: environmental remediation of VOCs and removal of NO_x from engine test facilities
- Future trends
- Summary

Technology-development motivators are regulatory, economic, and social

Regulatory

- New and/or more stringent regulations
Clean Air Act Amendment of 1990, Clean Water Act
Attendant MACT standards
- Enforcement of regulations

Economic

- Impact of regulations
- Costs associated with conventional methods

Social

- Environmental consciousness
- Health risks

The CAAA 1990 contains three titles closely related to new technologies (e.g., NTPs)

Title III (Air Toxics)

- Directly concerned with emission of hazardous air pollutants (HAPs)
- Established standards for 189 listed chemicals

Title IV (Acid Rain)

- Reduction of SO_x/NO_x emissions

Title VI (Stratospheric Ozone)

- Phase out of VOCs

MACT (Max Achievable Control Technology) Standards

- Calls for state-of-art pollution control equipment
- Require changes in equipment, processes, treatment

Non-thermal plasmas (NTPs) are a type of advanced oxidation & reduction process which use free radicals to decompose pollutants in the gas phase.

<p>Non-thermal plasmas are a type of AOP making use of "cold combustion" via free-radical reactions.</p>	<p>Applications</p> <ul style="list-style-type: none"> • Flue gases: e.g., NO_x & SO_x • VOCs: e.g., hydrocarbons & halocarbons • Odors: H₂S, others
<p>The key idea is to direct electrical energy into favorable chemistry for oxidizing and/or reducing pollutants to more manageable forms (simpler or mineralized terminal products).</p>	<p>Potential Advantages</p> <ul style="list-style-type: none"> • In-situ generation of chemical reactants • No added fuel (greenhouse gases) • Simultaneous removal of multiple pollutant species • Electronic feedback for optimal process control.

Historically, Advanced Oxidation Processes (AOPs) have involved ozone (O₃) and hydroxyl-radical (OH) reactions.

OH radicals were originally generated by the photolysis of O₃ and/or H₂O₂ in aqueous solution:*

The field has expanded to gas-phase processes in which both oxidative and reductive radicals are generated by electron-induced dissociation:

Not the whole story - O₃ & H₂O₂ can directly generate OH in water.

Prospective applications of NTP technology to off-gas treatment:

Direct processing (single-stage equipment)

- Remediation of solvents extracted from soil or groundwater
- Processing of industrial stack-gases or flue-gases
- Control of air emissions from waste processing (e.g., incinerators)
- Control of air emissions from diesel motor-generators, jet engine test facilities

Indirect processing (staged equipment)

- Destruction of hazardous organic liquids
- Treatment of heterogeneous wastes
- Processing of special materials

Non-thermal Plasmas Decompose Pollutants Via Active Species Generated in the Process Gas

The radical production efficiency (G-value) depends on the gaseous electronics. Radical generation is mainly initiated by energetic-electron collisions.

$$G = f \left(\frac{k_{\text{rad}}}{V_d} \frac{E}{N} \right)$$

- E/N is the reduced field,
- V_d is the electron drift velocity, which depends on E/N,
- k_{rad} is the rate constant for radical formation (e.g., a dissociation rate constant, which depends on E/N), and/or other rate constants.

Gas-phase plasma chemical decomposition is driven by electron impact and radical attack.

(1) $e + X \rightarrow$ products

(2) $O, OH, N, \text{etc.} + X \rightarrow$ products

- The first reaction is dominant at large pollutant mole fractions.
- The second dominates at smaller mole fractions.

(More energy is directly absorbed by pollutant at high mole fraction, hence electron channel dominates.)

Plasma chemical decomposition of VOCs produces a variety of terminal products.

$e, O, OH, N, \text{etc.} + X \rightarrow$ products

- **Manageable products:** $CO_2, CO, Cl_2, HCl, COCl_2$
- **Undesirable products:** Other halocarbons, hazardous byproducts (e.g., DCAC - $CHCl_2COCl$); polymers
- **Secondary treatment:**
 $CO_2 + NaOH \rightarrow NaHCO_3$
 $CO + \text{catalyst} \rightarrow CO_2$
 $Cl_2 + NaHCO_3 \rightarrow NaCl + HCl + \dots$
 $HCl + NaOH \rightarrow NaCl + H_2O$
 $COCl_2 + H_2O \rightarrow 2HCl + CO_2$

Major de-NO_x Reactions in Moist Gas Mixtures w/o HCs

Primary Acid-Formation Pathways:

The presence of SO₂ recycles OH radicals & reduces effective de-NO_x energy cost

The OH radical then goes on to be used again in de-NO_x

Acid is also formed by the reaction

With ammonia (NH₃) addition, useful particulates (fertilizer) can be formed from NO_x

(Ammonium Nitrate fertilizer)

A generalized removal equation depends on plasma chemistry (radical yields), reaction chemistry, and applied plasma specific energy.

Generalized differential equation:

$$\frac{k[X] + \sum_i k_{S_i} [S_i]}{k[X]} d[X] = -G d\bar{E}$$

Integration with limits $[X]_0 \rightarrow [X]$ and $0 \rightarrow E$ gives:

$$\frac{[X]}{[X]_0} + \frac{\sum_i k_{S_i} [S_i]}{k[X]_0} \ln \frac{[X]}{[X]_0} - 1 = -\frac{G\bar{E}}{[X]_0}$$

For low degree of removal (i.e., $[X]/[X]_0 \sim 1 + \ln \{ [X]/[X]_0 \}$), an analytical solution is obtained:

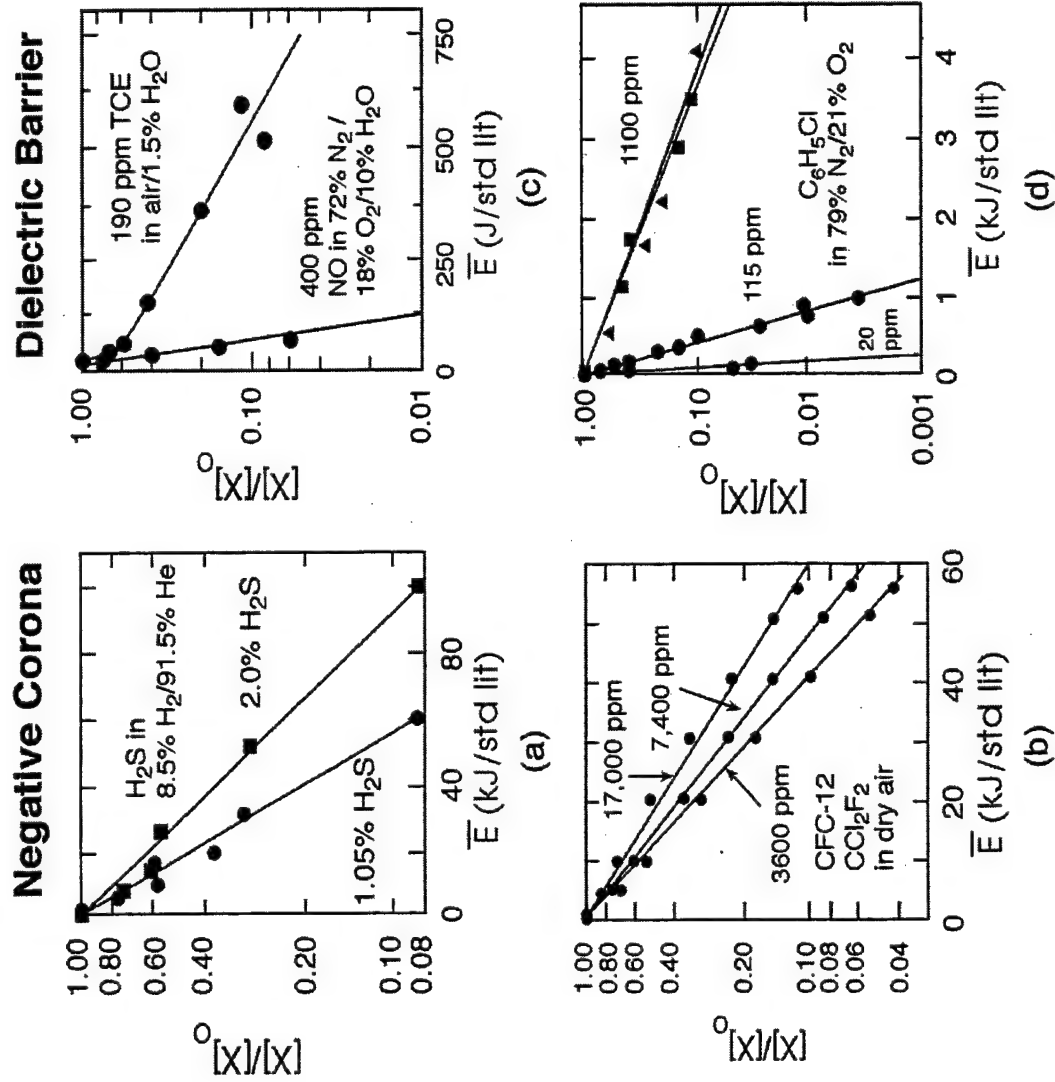

$$[X] / [X]_0 = \exp (-\bar{E} / \beta)$$

where

$$\beta = \frac{1}{G} \left([X]_0 + \frac{\sum_i k_{S_i} [S_i]}{k} \right)$$

When $k[X] \ll \sum_i k_{S_i} [S_i]$, the β -value and, hence the degree of removal $[X]/[X]_0$ shows no dependence on the initial concentration $[X]_0$.

Example removal data for various compounds

Scaling laws for pollutant removal

$$(1) \quad [X] = [X]_0 \exp (-\bar{E}/\beta),$$

where $[X]_0$ is the initial pollutant concentration, $[X]$ is the resulting concentration, \bar{E} is the applied specific energy (or plasma power divided by gas flow rate, P/Q), and β is the e-fold energy density. Supplying one β to the reactor reduces the concentration by $1/e$, 2β by $1/e^2$, and so on.

A useful figure of merit for the decomposition of pollutants is defined by the energy delivered to the plasma per hazardous molecule removed from the gas stream. At any instant, this can be expressed as the following quantity obtained by solving Equation 1 for \bar{E} and taking the derivative:

$$(2) \quad \gamma_i = -\frac{d\bar{E}}{d[X]} = -\frac{d[-\beta \ln(\frac{[X]}{[X]_0})]}{d[X]} = \frac{\beta}{[X]}.$$

This is the instantaneous energy cost per molecule removed; a more practically-useful parameter is the integral, or average, energy cost γ

$$(3) \quad \gamma = \frac{\bar{E}}{[X]_0 - [X]} = \frac{-\beta \ln(\frac{[X]}{[X]_0})}{[X]_0(1 - \frac{[X]}{[X]_0})}.$$

Here, the energy cost per molecule is expressed in terms of the β -value, the degree of removal, and the initial concentration.

Scaling laws for pollutant removal (cont'd)

Energy costs and degree of removal for NO removal in an NO-air mixture with one e-fold plasma specific energies of 50 J/liter and 20 J/liter. NO is one of several compounds whose β -value is not very sensitive to the initial concentration; therefore, the removal energy costs decrease as the concentration increases (note 200 ppm case vs 100 ppm case).

Example: NO_x - removal power requirement depends on exhaust gas flow rate, characteristic specific energy, and desired degree of removal.

- **Typical removal scaling:** $[X]/[X]_0 = \exp(-E_s/\beta)$,

where $E_s = P/Q$, plasma power divided by gas flow rate and β = specific energy for one e-fold removal.

For NO , $\beta \sim 10 \text{ J/lit (e-beam)}$; $\sim 50 \text{ J/lit (electrical discharge)}$.

- **Power requirement for one e-fold removal:** $P = Q \cdot \beta$.

Small Source:	Large Source:
$Q \sim 100 \text{ SCFM (2832 lit/min)}$	$Q \sim 1 \times 10^6 \text{ SCFM (2.83} \times 10^7 \text{ lit/min)}$
$P \sim 472 \text{ W (e-b)}, 2.4 \text{ kW (e-d)}$	$P \sim 4.7 \text{ MW (e-b)}, 24 \text{ MW (e-d)}$

Electron-Beam System

Serial-Mode NTP-Adsorber System

Serial-mode NTP-adsorber architecture. Disposal and/or regeneration economic advantage comes from reducing the load on the absorber or converting the pollutants to more easily-absorbed compounds.

Regenerative-Mode NTP-Adsorber System

Regeneration-mode NTP-absorber architecture. Economic and performance advantages may be gained by regenerating the absorbers off-line from pollutant capture, but employing on-site, rather than off-site handling.

Corona Radical Shower System

Schematic diagram of CRS reactor. Ammonia (NH_3) or methane (CH_4) are added to generate radicals that drive reactions leading to the formation of particulates; these particulates are then captured by the electrostatic precipitator. Some of the captured products are useful for agricultural fertilizer (e.g., ammonium nitrate, NH_4NO_3).

Cost comparisons for commercial Tecolytic™ modified dielectric-barrier NTP reactor system for de-NO_x/SO_x (flue-gas treatment)

Comparison of SVE off-gas technology cost attributes by general technology type:

Cost Effectiveness Attribute	Technology
Advantageous at low concentrations:	adsorption, free radical
Advantageous at higher concentrations:	thermal, free radical
Advantageous at low flow rates:	adsorption, free radical
Advantageous at higher flow rates:	thermal, free radical
Low capital cost:	adsorption, free radical
Low operational cost:	thermal, free radical
Recycling option:	adsorption
Highest DRE:	thermal, free radical
Performs well at high humidity:	thermal
Easily scalable:	free radical

Free-radical (NTP) technologies show advantages for spanning a broad range of concentrations and gas flow rates in remediation of hydrocarbons (~ 100 J/L β -value). Study from Cummings & Booth, LANL (1996).

Cost Comparisons for Soil-Vapor Extraction (SVE) Off-Gas Treatment Technologies

High Flow Rate, Short-term Remedial Action

High Flow Rate, Long-term Remedial Action

Figure 1. Cost Comparison at Low Flow Rate, Short-term Remedial Action

Figure 2. Cost Comparison at Low Flow Rate, Long-term Remedial Action

- **Figure 1** shows adsorption and free radical technologies are competitive at the low flow rate across a range of concentrations, over the short term
- The high capital cost of thermal technologies makes them an impractical choice for remediation under these conditions
- **Figure 2** shows adsorption technologies are cost effective only at low concentrations over the long term
- Free radical technologies are the most cost effective alternatives at concentrations above 200 ppm

Figure 3. Cost Comparison at High Flow Rate, Short-term Remedial Action

Figure 4. Cost Comparison at High Flow Rate, Long-term Remedial Action

- **Figure 3** shows adsorption and free radical technologies are competitive at the high flow rate only at low VOC concentrations over the short term
- Thermal technologies become competitive with adsorption at higher VOC concentrations
- Free radical technologies are the most cost effective alternatives at concentrations above 200 ppm
- **Figure 4** shows thermal and free radical technologies are the most cost effective choices at the higher flow rate over the long term
- The high operational costs associated with adsorption technologies causes them to lose cost effectiveness over the long-term schedule as concentrations increase

Los Alamos

Ideas for the future.

Finding market niches where NTP technology has significant advantages over conventional technologies in terms of:

- Increased efficiency and/or economics
- Increased selectivity or throughput
- Better control of final products and/or process
- Unique process streams

Potential examples:

- Regeneration of adsorbents (e.g., activated carbon) for environmental remediation and other air-pollution control applications
- Treatment of specialized radiochemical wastes

Two-Stage Thermal/Non-Thermal Hybrid Process for Hazardous Waste Destruction

Example: The two-stage process allows considerable flexibility in waste feeds and feed gases.

The operating conditions of the packed-bed reactor stage are flexible. We have demonstrated the ability to handle a wide variety of waste-feed surrogates, including those with high water content and different types of slurries.

In the non-thermal plasma stage, the yields of active species depend on the gas mixture.

A feed gas can be chosen to optimize the production of active species and the destruction of the waste.

Summary

- Most technical literature on treating air emissions with NTPs mainly presents phenomenological descriptions of reactor performance and, in most cases, does not provide a consistent way to compare and/or predict the scaling and optimization properties of different NTP systems.
- A simple way of comparing different types of NTP reactors, is based on the concept of: the plasma specific energy (electrical energy per unit volume deposited in the reactor active volume) required to remove a particular pollutant to a prescribed level in a defined exhaust-gas mixture and the associated yield (electrical energy cost per mass of pollutant removed).
- NTP is an emerging air-emissions control technology. Very few commercial systems exist. Also, for many emissions applications, the present forms of NTP technology are expected to be expensive (in terms of electrical power consumption) - and ancillary equipment (e.g., scrubbers) that may be necessary to handle treatment byproducts.
- Realizing the performance and economic shortcomings of stand-alone NTP reactors, the use of staged or hybrid systems to better match particular air-emissions control applications is proposed.
- Present trends for emerging NTP technologies are favorable. However, rigorous pilot-plant tests are required to provide further data and operating experience to more fully evaluate economic and performance projections.
